Problem 1:

Define $f(x) = \begin{cases} -3, & x = 4 \\ 4, & x = 5 \\ 0, & x \in [3,6], x \neq 4, x \neq 5 \end{cases}$ on the interval $[3,6]$.

Claim 1. f is Riemann integrable over $[3,6]$ and $\int_{[3,6]} f = 0$.

Proof. Let $\delta > 0$ be small, and define the partition $P = \{3, 4-\delta, 4+\delta, 5-\delta, 5+\delta, 6\}$. We calculate the lower sum:

$$L(f, P) = \sum_{j=1}^{5} \inf_{x \in I_j} f(x) \cdot \Delta x_j \tag{1}$$

$$0(4 - \delta - 3) - 3(4 + \delta - 4 + \delta) + 0(5 - \delta - 4 - \delta)$$
$$+ 0(5 + \delta - 5 + \delta) + 0(6 - 5 - \delta) \tag{2}$$
$$= -6\delta \tag{3}$$

And the upper sum:

$$U(f, P) = \sum_{j=1}^{5} \sup_{x \in I_j} f(x) \cdot \Delta x_j \tag{4}$$

$$0(4 - \delta - 3) + 0(4 + \delta - 4 + \delta) + 0(5 - \delta - 4 - \delta)$$
$$+ 4(5 + \delta - 5 + \delta) + 0(6 - 5 - \delta) \tag{5}$$
$$= 8\delta \tag{6}$$

Let $\epsilon > 0$ and impose the constraint that $\delta < \frac{\epsilon}{14}$. Then, $U(f, P) - L(f, P) = 8\delta - (-6\delta) = 14\delta < 14\frac{\epsilon}{14} = \epsilon$. Therefore, $\forall \epsilon > 0, \exists P_\epsilon = P \in \mathcal{P}([3,6]), U(f, P_\epsilon) - L(P, \epsilon) < \epsilon$, so f satisfies Riemann's condition on the interval $[3,6]$. This is true if and only if f is Riemann integrable over $[3,6]$. Then, since $L(f, P) \leq L(f) \leq U(f) \leq U(f, P)$, we have for a small $\delta > 0$ that $-6\delta \leq L(f) \leq U(f) \leq 8\delta$, and since when δ is arbitrarily small, -6δ and 8δ will be arbitrarily close to 0, so $0 \leq L(f) \leq U(f) \leq 0$, implying that $L(f) = U(f) = 0$ and equivalently that $\int_{[3,6]} f = 0$. $\square$

Problem 2:

Define $f(x) = \begin{cases} 3, & 1 \le x < 2 \\ 2, & 2 \le x \le 4 \\ 4, & 4 < x \le 5 \end{cases}$ on the interval $[1, 5]$.

Claim 2. *f is Riemann integrable on $[1, 5]$ and $\int\limits_{[1,5]} f = 11$.*

Proof. By inspection, $\forall x \in [1, 5], |f(x)| \le 4$, therefore f is bounded on $[1, 5]$. Define the finite sequence of intervals $a_1 = (2 - \frac{\epsilon}{8}, 2 + \frac{\epsilon}{8})$ and $a_2 = (4 - \frac{\epsilon}{8}, 4 + \frac{\epsilon}{8})$. Then, the set of discontinuities of f in $[1, 5]$, that is $\{2, 4\}$ is a subset of $a_1 \cup a_2$. Furthermore, $(2 + \frac{\epsilon}{8} - (2 - \frac{\epsilon}{8})) + (4 + \frac{\epsilon}{8} - (4 - \frac{\epsilon}{8})) = \frac{\epsilon}{2} < \epsilon$, therefore the set of discontinuities of f on $[1, 5]$ has Lebesgue measure 0 and is bounded on that same interval. This is true if and only if f is Riemann integrable on $[1, 5]$.

Let $\delta > 0$ be small and define the partition $P = \{1, 2 - \delta, 2 + \delta, 4 - \delta, 4 + \delta, 5\}$. We calculate the lower sum:

$$L(f, P) = \sum_{j=1}^{5} \inf_{x \in I_j} f(x) \cdot \Delta x_j \tag{7}$$

$$= 3(2 - \delta - 1) + 2(2 + \delta - 2 + \delta)2(4 - \delta - 2 - \delta)$$
$$+ 2(4 + \delta - 4 + \delta) + 4(5 - 4 - \delta) \tag{8}$$

$$= 11 - 3\delta \tag{9}$$

And the upper sum:

$$U(f, P) = \sum_{j=1}^{5} \sup_{x \in I_j} f(x) \cdot \Delta x_j \tag{10}$$

$$= 3(2 - \delta - 1) + 3(2 + \delta - 2 + \delta)2(4 - \delta - 2 - \delta)$$
$$+ 4(4 + \delta - 4 + \delta) + 4(5 - 4 - \delta) \tag{11}$$

$$= 11 + 3\delta \tag{12}$$

As in the previous problem, we have $L(f, P) \le L(f) \le U(f) \le U(f, P)$, so for an arbitrarily small $\delta > 0$, we have $11 - 3\delta \le L(f) \le U(f) \le 11 + 3\delta$ therefore $11 = L(f) = U(f)$, or equivalently $\int\limits_{[1,5]} f = 11$. $\qquad \square$
